SELECTED TRANSLATIONS OF
ABSTRACTS IN REFERATIVNYY ZHURNAL - BIOLOGIYA, No. 2, 1959

This report consists of complete translations of the Russian-language abstracts of articles, which were originally published in the Sino-Soviet bloc and in Yugoslavia.

The Soviet subject classification system used in the original Russian language abstracts has been followed in this publication.

POLAND / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6199

Author : Birecka, H.; Tucholka, Z.; Lisiewicz, A.
Inst : Poznan Chemical Institute
Title : Studies on the Utilization of Fertilizers in
the Cultivation of Summer Grains in Rows

Orig Pub : Roczn. nauk rolnych, 1957, A76, No 1, 31-41

Abstract : The results of 11 field experiments, conducted
at the Chemical Institute in Poznan, concerning
the use of nitrogen and potassium fertilizers
together with granulated P_c in rows, are given
in this paper. Higher yields were obtained in
all cases when a full dose of N was applied in
the rows than when the same fertilizer was broad-
cast. An even higher increase in the yield was

Card 1/2

POLAND / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6199

obtained by the simultaneous row application of
N and granulated P_c. Small doses of N applied
in rows with additional quantities broadcast to
make up a full dose give better results than
the application of the full dose by broadcast-
ing alone. -- A. F. Khlystova

Title : Biological Peculiarities of the Breed of Winter
Wheat Obtained From Seeds Taken From the Stalks
Formed in the Spring

Orig Pub : Byul. nauchno-tekhn. inform. L'govsk. opytno-
selekts. st., 1958, vyp 1, 53-56

Abstract : Data resulting from a study of the effect of
spring stalk-formation on the biological char-
acteristics of winter wheat is given. The
cessation of winter properties and the appear-
ance of summer forms can take place even in the
case of a single pre-winter sowing. The loss of

Title : The Improvement of Conditions of Nutrition of
Winter Wheat, After Preceding Crops Which Were
Plowed

Orig Pub : V sb. n.-1. in-ta maslichn. i efiro-maslichn.
kul'tur za 1956 g., Krasnodar, "Sov. Kuban'",
1957, 218-221

Abstract : Fertilizers, even when they are introduced only
in small doses in order to help the growth of
winter wheat sowed after preceding crops which
had been plowed, increase its yield considerably.

Card 1/2

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6203

Fertilizers, when they are introduced during pre-sowing cultivation, are highly beneficial to the yield. Granulated P_0 is particularly effective. Good results were obtained with an early top dressing by using phosphorous-nitrogen fertilizers. When there is a dearth of mineral fertilizers, they should be used first in the fields, where wheat follows corn. --
Ye. I. Saks

Title : The Sowing of Durum Wheat by Separate Seed
Fractions
Orig Pub : Zemledeliye, 1957, No 3, 80-82
Abstract : The results of the study at the Chkalov agricul-
tural institute (1954-1956) of the norms of
sowing of durum wheat (Melanopus 69 variety)
in relation to the size of seeds is given in
this paper. Excessive density of sowings
(6.5 millions for small seeds, 5.5 mil. for
medium and large sizes on 1 ha) causes the
plants to become depressed. This phenomenon

Card 1/2

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6209

is accompanied by a sharp decrease on their yield. It is recommended to sow durum wheat separately, by fractions, with different norms of sowing. Data on the yield in various fractions and sowing norms, are given. In the central zone of the Chkalov oblast' it is recommended to sow durum wheat seeds when their absolute weight is under 25 g in quantities of 5.5 mln per 1 ha. When their weight is 30-32 g the quantity should be 4 - 4.5 mln; and when the weight is over 40 g, the quantity should not be under 3.5 mln grains per ha. -- G. N. Chernov

Title : The Effect of Agrometeorological Conditions on
the Yield of Wheat Sowed During Various Periods

Orig Pub : Tr. Odessk. gidrometeorol. in-ta, 1958, vyp 16,
3-8

Abstract : Experiments were started in the fields of the
All-Union Selection-Genetic Institute in the
fall of 1955 to study the effect of the periods
of sowing of winter rye on the yield of the
green mass in the south of the Odessa oblast'.
The seeds of winter rye of the Odesskaya 1 variety
were, at intervals of 10 days, sown over the

Card 1/2

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6215

black-fallows in seven different periods between August 20th and October 20th. The depth of sowing was 6 - 7 cm. The green mass was harvested twice; the first time was on May 15th for all periods of sowing. The second time, the plants were harvested during the phase of ear formation; the harvesting was carried out separately for plants belonging to different periods of sowing. The best period for winter rye sowing was between September 10th and 20th. The reasons for the lowering of the yield corresponding to other periods of sowing are analyzed. --

out in June of the next year. The more resistant varieties were contaminated separately with 7 strains among the groups A, C, D, B, which occur in the hothouse, and with strain F, which originated spontaneously from B. 88% of the barley plants were contaminated by strains A and C. Six varieties, belonging to the hexastichon var. hybnum morphological group displayed a high resistance against all fungus strains; six varieties were resistant against some of the strains. Varieties, which were mostly of recent origin (6%) varied with regard to their susceptibility to disease. These experiments were carried out at the Phytopathological Institute, University of Halle and at

Inst : Khar'kov Agricultural Institute
Title : The Effect of Presowing Treatment of Barley
Seeds on Their Productivity

Orig Pub : Zap. Khar'kovsk. s.-kh. in-ta, 1958, 15(52),
51-62

Abstract : The experiments took place under laboratory
and field conditions in 1954-1955. They in-
volved summer barley grown with two fertilizers
in the following variations: soaking of the
seeds in water at an initial temperature of 70°
during 24 hours with subsequent drying up to
115-118% of the initial weight (I); heating

Card 1/2

Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6218

in water at a constant temperature of 40° during
3 hours with drying as above (II); soaking
during 6 hours in water at a temperature of 18-
19° and heating during 1 hour at 40° (III);
heating of dry seeds during 1 hour at 40°
(IV); soaking in an infusion of branched wheat
during 24 hours with drying as above (V).
The first and the fifth variations were most
effective. The Bibliography contains 31
titles. -- B. I. Kazachek

Title : Preliminary Study of the Resistance of Oat
Varieties to the Swedish Frit Fly in the Fields
Orig Pub : Hodowla rosl. aklimat. i nasienn, 1957, 1,
No 56, 723-743

Abstract : Later sowings of oat undergo more damage than
the early ones. The Udych Zhulty, Przebuy II
and L. P. 214 varieties are resistant to the
Swedish fly. Proporchik, Mlokhovskiy, Seletskiy,
Teodoziya, Antonin'ski Byaly and Byaly Mazur -
are more susceptible to this pest.

Title : The Selection of Corn Parental-Pairs in Order
to Obtain Productive Hybrids
Orig Pub : Byul. nauchno-tekhn. inform. Arm. n.-i. in-t
zemledeliya, 1957, No 3, 3-5

Abstract : Data, collected at the Parakarsk Experimental
Base as a result of trials of varieties, var-
ietal strains, inter strain hybrids, hybrid
populations and inter varietal hybrids in
1955-1960, is given in this paper. All var-
ieties were distributed into 5 groups accord-
ing to the time of sowing. Dent corn varieties

Card 1/

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6221

are more productive than the flint corn. The yield of prospective varieties attained 23 - 35 cwt/ha. The hybrid populations, double inter-strain, and varietal strain hybrids produce the best yield of cobs and of green mass (30 - 49 cwt/ha); simple inter strain hybrids are less productive. The highest yield (28 - 47 cwt/ha) was produced by the following combinations: Flint white Gruzinskaya No 10 x Sterling, Flint yellow Tumanyan x Gorskaya yellow, Flint yellow Tumanyan x Voronezh 76, Grushevskaya x Early Gorets, Early Gorets x Minnesota 13 and Char'kov white dent x Sterling. These parental pairs are recommended to obtain inter varietal hybrid seeds. -- A. F. Khlystova

Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6230

Gorets, white dent Khar'kov varieties produced a low yield of green mass (138 - 184 cwt/ha) but gave the highest yield of grain (12.3 - 15.9 cwt/ha). The best results in obtaining cobs without husks are gotten from the Rumanian yellow flint variety (28.8 cwt/ha), which is recommended by the institute for seed sowings. The optimal preceding crops for corn is "Rzhanishche" variety of rye which should be sown in the first ten days of May in the southern part of the oblast. It should be sown in the second ten days of May in the northern part of the oblast. -- N. G. Buyakovich

Inst : Yaroslavl' Agricultural Institute
Title : Study of Methods Designed to Increase the Yield of Corn

Orig Pub : Tr. Yaroslavsk. s.-kh. in-ta, 1957, 4, 3-19

Abstract : The best sowing time in experiments carried out at the Yaroslavl' Agricultural Institute on medium argillaceous soil in 1956 was 25 - 30 May. The seeds were put in at a depth of 5 cm. The soil temperature at this depth was higher by 1.3 - 1.8° than at a depth of 8 cm. The sprouts came out a day earlier; the number of empty hills diminished from 6 to 5.6 when sowing

Card 1/3

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6231

took place on 25 May and from 3.5 to 1.3% - when it was done on 30 May. The green fodder yield increased by 20 - 8 cwt. The highest yields of Voronezh 76 cobs were obtained with 3 plants in a 60 x 60 hill. The yield was somewhat lower in a 70 x 70 cm hill. The Krasnodarsk 1/49 variety produced 623 cwt/ha of green stuff with 3 plants per 45 x 45 hill. The yield was 500, 2 cwt in a 60 x 60 hill. With 5 plants in a hill of 70 x 70, the yield was 447.1 cwt/ha. The yield of green mass in sowings of corn with peas was higher by 62.5% than in pure sowings. The increase in the percentage of digestible protein was 89.9%. The highest yield was obtained in squares of 45 x 45 with 3 plants

Card 2/3

Inst : Saratov Agricultural Institute
Title : Certain Problems of Agrotechny for Corn Grown
on Chestnut Soils

Orig Pub : Vestn. s.-kh. nauki, 1958, No 4, 55-59

Abstract : Experiments were carried out at the Krasnokutsk
Experimental Station, at the training experi-
mental farm of the Saratov Agricultural Insti-
tute, and at the Kolkhozes of the Saratov
oblast. The effects of the following methods
of plowing on the yield of corn was studied:
with a moldboard at a depth of 20-22 cm (I);
at a depth of 32 cm (II); at a depth of 20-22

Card 1/2

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6232

cm with a deepening of 10 cm (III); and without
a moldboard at a depth of 35 - 40 cm (IV). The
effect of fertilization and irrigation with
various kinds of plowing was also studied.
Method I produced better results than method IV
on clogged soils. The results obtained with
methods I and IV were similar on pure soils.
Plowing according to method III produced worse
results than methods I and IV. The application
of fertilizers and irrigation in the case of
deep plowing increases the yield considerably.

Sowings in the Non-Chernozem Belt

Orig Pub : Vest. s.-kh. nauki, 1958, No 4, 45-48

Abstract : Experiments were carried out at the Belorussian
Agricultural Institute on sandy loam, medium
and heavy argillaceous loams in 1955-1957.
Minnesota 13 extra corn was sown according to
the square-pocket method (70 x 70 cm). Culti-
vation was carried out three times in two
directions. Deep mellowing on 10-12 cm during
the whole period gives negative results. The

Card 1/2

Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6234

best results were obtained with shallow culti-
vation on 4-6 cm. Hilling gave positive re-
sults only on light soils during a moist
summer; it is harmful on heavy soils. The main
reason for the lowering of yields in case of
cultivation between rows is the damage inflicted
to the roots. It is recommended to use shallow
cultivation which is sufficient for destroying
weeds and safe for corn roots. -- B. I. Kazachek

Agricultural Institute. The supply of moisture
in the soil under the plants, the nutrient
supply, growth and development of plants, the
yield of grain all are higher in the case of
plowing without moldboard. The highest yield
of corn was obtained when organic-mineral
fertilizer + cluster sowing were used. The
best yield for winter wheat was obtained by
using P8K10 fertilizer and plowing in rows. --

Title : The Effect of the Density of Plants in Hills
on the Yield of Corn

Orig Pub : Byul. nauchno-tekhn. inform. Chelyab. gos.
s.-kh. opytn. st., 1956, No 1, 7-10

Abstract : Field experiments were carried out at the
Chelyabinsk experimental station in 1955-1957
in order to find out the optimal density of
corn (Krasnodarskaya 1/49 and Kazanskaya 128
varieties) in hills so as to obtain the highest
possible yield. The yield of green mass is a
direct function of the density of the plants in

Card 1/2

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6238

the hill - it increases with the density of
sowings. It is necessary to leave 4 - 5 plants
in a hill, when corn is cultivated for green
fodder and silage, and no more than 2 - 3,
when it is cultivated for grain. -- E. I. Saks

Orig Pub : V sb.: Kratkiye itogi nauchno-izsled. raboty (Kubansk. ris. opyt. st.) za 1956 g., Krasnodar, "Sov. Kuban'", 1957, 99-103

Abstract : An experiment was carried out under field conditions with the Krasnodarskiy 424 and VROS 213 varieties in order to establish the causes of low germination of seeds when hybridization of rice is carried out. The flower scales were forced open by putting straws among them

Card 1/3

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6242

during the formation of panicles in the Krasnodarskiy 424 variety; spikelets opened before, during and after blooming. The flower scales on the VROS 213 variety were cut off, as in usual castration. When the flower is forced open, ovary growth stops early and only an insignificant part of the ovaries ripens. The spikelets of the lower part of the panicle suffer most from these unfavorable conditions. When castration is carried out by cutting off the flower scales, the destruction of ovaries goes on during the whole time of the development of the seed vessel. If the flower scales are cut before the beginning of the period of blooming, most ovaries are 1.5 mm large; the number of ovaries

(Kubansk. ris. opytn. st.) za 1956 g.
Krasnodar, "Sov. Kuban'", 1957, 87-91

Abstract : The results of vegetation experiments made with
late ripening Bol'shevik and early Bozu
varieties are given in this paper. The periods
when the plants pass through the gametogenesis
stage were established by how long rice is
allowed to remain without blue-violet rays. This
was achieved by putting the plants under a

Card 1/2

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6243

tartrazine filter. The lack of blue-violet
rays was most effective on the Bol'shevik
variety during the first period of panicle
formation; on the early Bozu, the results were
most noticeable during the period of formation
of stamen tubercles. The gametogenesis stage
in early sowing starts after the luminous stage
and lasts till the formation of staminal
tubercles in the case of the Bol'shevik variety.
Late sowings prolong the course of gametogenesis
stage. The lack of blue-violet rays increases
the growth of plants in height. Bibl. 11
titles. -- T. I. Shapiro

Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6255

capacity of sorghum for green fodder, silage
and grain in comparison with corn and Sudan
grass was studied at the experimental station
of field cultivation of the Kishenev Institute.
Chemical analyses of the green mass, silage
and grain were carried out. Time and methods
of sowing, norms of sowing, time of mowing
were studied. Mixed sowings of sorghum with
corn and leguminous crops, as well as stubble
sowings of sorghum after various crops were
tested. Appropriate recommendations are given
on all these problems and they permit to affirm
the expediency of introducing sorghum as a
staple crop in Moldavia. The expediency of
increasing the sowings of Chinese sugar cane

Title : Experimental Cultivation of Sorghum in
Stavropol'ye

Orig Pub : Materialy po isuch. Stavropol'sk. kraya,
vyp 8, 1956, 43-59

Abstract : Data, supplied by variety trial plots,
scientific research, institutions, as well
as by kolkhozes and sovkhoses cultivating
sorghum on large areas, showed that in dry
regions, on salted soils, and in dry years, the
yield of sorghum exceeds that of corn. Of
particular significance was 1955 - a dry year,

Card 1/2

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6256

when sorghum was the only crop, which produced grain, green mass and silage in some regions. Good results were obtained by cultivating sorghum in the Manych pastures, where yearly precipitation is 150-200 mm. The biology and the agrotechny pertaining to sorghum are described. The best varieties for Stavropol'ye are: Karlikovaya Dzhugara 185 [dwarf milo], Ranniy Yantar' Dnepropetrovskiy, Oranzhevoye 450, Krasnyy Yantar' 271/585, Stavropol'skiye 98. -- N. N. Kuleshov

Title : Sorghum on the Tadzhikistan Non-Irrigated Land

Orig Pub : S.-kh. Tadzhikistana, 1957, No 7, 24-28

Abstract : The Institute of Animal Husbandry, TadzhSSR, carried out experiments in 1952 and 1953 on the sowing of sorghum on unirrigated land in the driest regions of the republic. Early Gaolyan 178 variety produced 34.3 and 26.5 cwt/ha of hay. The vegetation period before ripening lasted only 66 days. Sowing was done on March 20th, sprouts appeared on April 2nd;

Card 1/3

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6257

seeds ripened on June 7th. Experiments conducted in subsequent years showed that in the case of fall plowing, when the sowing takes place at the end of March - beginning of April with a distance between rows of 60 cm, and when the norm of sowing is 6 - 7 kg/ha, the early sorghum varieties produce good crops of green mass and hay on these unirrigated plots. Late ripening varieties are not suitable there, because their racemes dry up and do not produce seeds. Corn cannot grow under these conditions (absence of moisture). Sorghum gives high yields of green mass and of silage, if the soil is watered. It gives an aftermath which is equal in productivity to the first mowing, it is mowed for

Card 2/3

USSR / Cultivated Plants. Grains. Legumes. Tropical M-1
Cereals.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6257

the first time in the period when panicles appear. The first mowing (August 9th) on watered soil produced 406.7 cwt/ha of green mass in 1956 in the Gissar Valley, kolkhoz im. Stalin. After the second mowing October 9th the yield was 424.3 cwt/ha. When the soil is watered, it is possible to have two harvests during the vegetation period. A high sugar content in the stalks of sorghum makes it an excellent raw material for silo. It can be utilized as a component for ensilage for crops, which do not lend themselves readily to ensilage. -- N. N. Kuleshov

Title : Respiration Rate of Potato Tubers During Storage

Orig Pub : Agrobiologiya, 1958, No 2, 66-71

Abstract : The respiration rate of tubers during 6 months of storage was determined in a desiccator (Ella variety). The respiration of tubers in cellar at a temperature of 11.5 - 16° was least slowed down. One kg of tubers exhaled 2 - 3 mg of CO₂ in an hour. Exhalation of CO₂ in a laboratory at 15 - 18° increased up to 7 mg in December and 11 mg in March. The respiration of the tubers sown in the spring was more

Card 1/3

USSR / Cultivated Plants. Potatoes, Vegetables, Melons. M-2

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6264

intensive in a refrigerator than in a cellar; the respiration of tubers sown during the summer was more intensive than in the laboratory. The exhalation of CO₂ at the end of the storage period reached 12.2 mg. Under the influence of high concentrations of CO₂, the eyes dried up and the lenticels became affected. The loss of weight was 7% in laboratories. In cellars, it was 4.7 among tubers sown in the spring and 2.5% among tubers sown in the summer. It was 0.7% in desiccators, when they were covered with earth, and 2.7% - in refrigerators. The loss of weight in experimental cells was 10% when the humidity of the air was 100%. The tubers contained 5% sugar in refrigerators, 1.2% in cellars,

Title : Seed Cultivation of Jerusalem Artichokes in
the Central Rayons of the Non-Chernozem Belt

Orig Pub : Selektsiya i semenovodstvo, 1958, No 2, 30-35

Abstract : According to tests carried out during experiments conducted at the Timiryazev Agricultural Academy field station, the most productive varieties and forms of Jerusalem artichoke were: Belaya Urozhaynaya, Saratovskaya, Hybrid 120 and Vadim. Liquid manure spread over the sprouts in doses of 10 t/ha on a seed field used for three years increased the yield of tubers by 30%. It is preferable to

Card 1/3

USSR / Cultivated Plants. Potatoes, Vegetables, Melons. M-2

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6273

harvest the tubers in order to get seeds in the spring, because in this case, their yield increases by 15 - 20%. The above-ground mass of the Jerusalem artichokes is cut on the seed plots before the start of frost. The Vadim and Saratovskaya varieties from the industrial point of view are the most interesting with regard to the central regions of the non-chernozem belt, because they produce comparatively high yields of green mass and tubers and they hibernate satisfactorily. The propagation of Jerusalem artichokes can also be effected by accelerated means. To obtain this, buds, weighing 2 - 3 g, are cut away from large tubers and planted in hothouses or in peat compost blocks. After 20 - 25 days, when the

Title : Jerusalem Artichokes

Orig Pub : Nauka i peredov. opyt v s.-kh., 1958, No 3,
44-45

Abstract : Jerusalem artichokes (Rozovyy and Belyy Urozhaynyy varieties) were planted according to the square-pocket method (60 x 60 cm). There were two tubers in a hill. The experiment was conducted at the Bryansk Selection Station in 1957. 300 - 400 cwt/ha of green mass were obtained in the middle of September with a full mineral fertilization and liming. The yield was 200 - 270 cwt/ha at the end of

Card 1/2

USSR / Cultivated Plants. Potatoes, Vegetables, Melons. M-2

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6274

September. The yield of the Rozovyy variety was higher by 30 - 33% than that of Belyy Urozhaynyy. It is recommended to utilize Jerusalem artichokes for hog pasture in the fall (after harvesting of the green mass) and in the spring.

Title : Chinese Cabbage Culture

Orig Pub : Sad i ogorod. 1958, No 7, 19-21

Abstract : The practice of growing Chinese cabbage as a filler for tomatoes and cucumbers in hothouses was developed in Khibiny. The first crop of cabbage is carried out 22 - 25 days after sowing. The yield in a hothouse, when cabbage is grown as an independent crop, reached 4 - 6 kg/m²; in open ground the yield is 300 - 350 cwt/ha. In order to insure that seeds ripen uniformly, it is necessary to vernalize the seeds for 24 - 36 hours in a warm place and

Card 1/2

Title : Biological Reasons Why Onion Leaves Should
Be Cut at Harvest Time
Orig Pub : V.S., Sad i ogorod, 1958, No 7, 11-12

Abstract : The main losses of onions during storage are
caused by neck rot, according to the data
collected by the Scientific Research Institute
of Vegetable Crops. The causal agent of this
disease produces spores on the scales of the
bulb. The conidia of the fungus rest in the
soil, after the destruction of the bulb. The
fungus develops on leaves and penetrates into
the bulb when onions are dried in the field

Card 1/2

Their effect as preceding crops for winter wheat was also studied in experiments conducted during the last 5 - 6 years, mainly at the Institute of Plant Cultivation of the Acad. of Sci. BPR and at agricultural high schools in Sofia and Plovdiv. The effect of fertilizers on the yield of above-ground and root masses of perennial grass mixtures was also studied. The following grasses were experimented on singly and in mixtures as annual winter crops: red and white clovers, esparsette, alfalfa, smooth brome, timothy, rye grass, red top, rye, winter vetch, fodder peas, wheat, fescue grass (meadow and red), dew grass. Experiments were conducted on vetch,

Title : Characteristics of the Water Content in
Perennial Grasses

Orig Pub : Izv. Sibirsk. otd. AN USSR, 1958, No 1, 141-149

Abstract : Experiments were carried out at the botanical garden near Ufa with red clover, sickle alfalfa, sainfoin (Hungarian and Trans-Caucasian), white sweet clover (*Melilotus alba*) smooth and meadow brome, slender wheatgrass, *Roegneria fibrosa*, crested wheatgrass and *Agropyron umbricatum*. They were sowed without cover in the spring of 1953 and 1954. The content of water in leaves of perennial grasses

Card 1/3

USSR / Cultivated Plants. Fodder Grasses and Root Crops. M-3

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6294

diminished until the end of the vegetation period. This process is related to the aging of plasmatic colloids in the tissues. Leaves of perennial leguminous grasses contain more water than those of cereals. Leaves of wild perennial grasses contain less water than those of cultivated ones. The perennial grasses are disposed in the following order, according to the content of water in their leaves: among the leguminous - sweet clover, Hungarian, hybrid and Trans-Caucasian sainfoin, red clover, alfalfa blue hybrid, sickle alfalfa; among the cereals: crested wheatgrass and *Agropyron umbricatum*, smooth brome, *Roegneria fibrosa* and slender wheatgrass. The water retaining capacity diminished

Card 2/3

USSR / Cultivated Plants. Fodder Grasses and Root Crops. M-3

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6294

in the blooming phase in cereal perennial grasses and clover; it increased in sweet clover, sainfoin and alfalfa. The water retaining capacity of varieties and ecological types of red clover, hybrid and sickle alfalfa and smooth brome diminished with age. The author came to the conclusion that sweet clover, sainfoin, smooth brome and wheatgrass can be sown in dry steppe and forest-steppe regions of the republic; hybrid and sickle alfalfa can be sown in better irrigated and forest-steppe regions; red clover, slender wheatgrass and *Roegneria fibrosa* can be sown in properly irrigated forest steppe and forest regions. --

Title : The Selection of Common Vetch

Orig Pub : Byul. Ukr. n.-i. in-ta rastenievodstva,
selekto. i genet., 1958, No 2, 17-18

Abstract : Different forms and varieties of peas were studied at the institute in 1955-1956 in order to select early ripening fodder varieties with fine seeds. The weight of 1000 seeds of various varieties of vetch in the institute's collection fluctuated between 100 and 448 g during 1956. Vetch of the Khar'kovskiy Bl variety is ready for mowing 58 - 70 days after

Card 1/2

sprouting; its height reaches 1.5 - 2 m. The Khar'kovskiy 131 variety was grown at the Khar'kov Selection Station during 1955. It was a favorable year for late ripening varieties. When mixed with oats it produced 309 cwt/ha of green mass; the yield was 370 cwt/ha when it was sown alone. The yield of grain reached 42.5 cwt/ha during the years when there was sufficient precipitation. The coefficient of propagation of seeds was 85, when sowing was done in broad rows (39 cm); it was 64 when the distance between rows was 26 cm wide. -- E. A. Okorokova

Agriculture

Title : Common Vetch in Arid Steppes

Orig Pub : Kolgospnik Ukraini, 1958, No 3, 18

Abstract : Data, compiled by the Ukrainian Sci.-Res.
Institute of Irrigated Agriculture on the
yielding capacity of vetch varieties cultivated
for green mass in the Southern Ukraine during
1957, is given in this paper. Of all tested
varieties, the greatest yield of green mass -
195 cwt/ha (42.9 cwt/ha of hay) - was produced
by the Uladovskiy 387 variety. Recommendations
on cultivation of vetch for hay are given.

Title : The Field Pea as a Valuable Crop in the
Northern Districts

Orig Pub : Nauka i peredov. opyt v s.-kh., 1958, No 3,
42-43

Abstract : The field pea of the Alexandrovskaya 231
variety mixed with oats and white mustard in
various proportions was sown in the All-Union
Institute of Fodders in 1956-1957. The yield
of field peas was higher when it was sown
alone, but the plants lodged and this made
mechanized harvesting difficult. A yield of
peas of 33 cwt/ha (including 15 cwt of field

Card 1/2

USSR / Cultivated Plants. Fodder Grasses and Root Crops. M-3

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6313

pea) and 40 cwt/ha of straw was obtained in 1957, when a mixture of 90 kg/ha of peas and 133 kg of oats was sown. The norm of sowing of 70 kg/ha of field pea and 150 kg/ha of oats was found to be best at the Ust'-Kulomskiy variety testing section (KomiASSR). Good results were obtained by sowing 146 kg/ha of field pea and 9 - 12 kg of mustard in order to obtain grain. The grass did not lodge, the yield of grain of field peas was 14.4. For mustard the yield was 2.7 - 3.6 cwt/ha. The highest and the most stable yields are produced with the Alexandrovskaya 231, Falenskaya 42 and Spartanets field pea varieties. -- Ye. A. Okorokova

Title : Foxtail Millet in Relation to the Reaction of the Medium

Orig Pub : Vestn. Mosk. un-ta, Ser. biol. pochvoved., geol., geogr., 1957, No 2, 111-117

Abstract : Vegetation experiments were conducted in sandy crops with various medium reactions: weakly alkaline medium (pH 7.5), neutral (pH 6.5), weakly acid (pH 5.5), strongly acid (pH 4.5). These experiments were conducted by the Department of Agricultural Chemistry of Moscow State University in 1954 and 1955. The reaction of the medium was established every other day

Card 1/2

USSR / Cultivated Plants. Fodder Grasses and Root Crops. M-3

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6316

during the whole vegetation period by adding H_2SO_4 and NaOH in drip pans. Foxtail millet had the greatest sensitivity to the acid reaction in the initial period after sprouting (~30 days). The germination with a neutral reaction was 65%; the number of lost plants was 0. At the same time the results were, respectively, 55 and 22% with an acid reaction. Weakly acid reactions are as favorable to plants as neutral ones. Weakly alkaline reaction had an unfavorable influence only in the initial period. The acid reaction caused a disturbance in the carbohydrate and protein metabolism; it brought about an accumulation of non protein N in foxtail millet; the content of Ca diminished whereas the content of P and K increased. --

Title : The Selection of Mangel-Wurzel Varieties

Orig Pub : Za vysokom urodu, 1957, 5, No 4, 77-78

Abstract : Semchitsa (Czechoslovakia) Scientific Research Institute divides mangel-wurzel according to its productivity and starch content in 3 basic groups: coarse, semi-saccharine and saccharine. The coarse variety occupies by its yield of the fodder mass the first place, but it takes the last place by its starch content. Three [sic!] coarse mangel-wurzel varieties are cultivated: Kostelets, Barres, Yellow Unicum and Buchan

Card 1/3

CZECHOSLOVAKIA / Cultivated Plants. Fodder Grasses and Root Crops. M-3

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6324

Yellow Valets. The two of the last named varieties exceed the half saccharine one by 10 - 20% in weight. Coarse mangel-wurzel grows almost at the surface of the earth; this circumstance facilitates the harvesting of the crop, but it deteriorates in storage. The yielding capacity of semi-saccharine mangel-wurzel is less than that of the coarse varieties. It contains more nutrition substances and produces more haulm. It requires a deeper soil cultivation. Red semi-saccharine mangel-wurzel contains the largest amount of starch. Saccharine mangel-wurzel has the greatest content of starch in comparison with other varieties, but the weight of its edible

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6328

Application of fertilizers in crop rotations with alfalfa on takyr-like soils at the Ioltan Station produced a yield of cotton wool of 26 - 43 cwt/ha. When cotton was sown as a single crop with the introduction of a fertilizer, the yield was 16 - 21 cwt/ha. The increment in the yield of cotton wool on dark Sierozem soils near the city of Chimkent was 1.3 - 1.6 cwt/ha in comparison with the case, when cotton was sown as a single crop. The content of humus, of N and of P in the soil increases appreciably, when crop rotation is applied. A tendency toward an increase in the cotton yield with every new rotation is observed. -- S. A. Nikitin

Title : The Effect of Sowing Methods on Fruit Bearing
of Various Cotton Varieties

Orig Pub : Tr. Azerb. s.-kh. in-ta, 1957, 4, 53-66

Abstract : Experiments on the study of the fruit bearing
of cotton varieties 1298 and 2018/2 with 6
variants of plant disposition: 60 x 60 x 3,
60 x 45 x 3, 50 x 50 x 2, 45 x 45 x 1,
45 x 45 x 3, 70 x 15 x 1 were carried out at
the training farm (uchkhoz) of the Azerbaydzhan
Agricultural Institute. The 1298 variety had
a higher fruit bearing potential. The greatest

Card 1/2

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6331

number of fruit-elements is formed in both
varieties with the square-pocket sowing.
Sowing, according to the scheme 50 x 50 x 2,
produces the least percentage of dropping of
bolls. The size of bolls varies greatly
at the 2018/2 variety depending on the disposi-
tion of plants, but no great difference is
noticed in the size of fruit organs in the 1298
variety with any disposition of plants. The
highest yield in both varieties was obtained
with the scheme 50 x 50 x 2. -- B. L. Klyachko-
Gurvich

Title : Cross Pollination of Cotton of the Azerbaydzhan
Varieties

Orig Pub : V sb.: Ref. nauchno-izsled. rabot po
khlopkovodstvu. Tashkent, AN Uz SSR, 9-21

Abstract : Data on gradual decline of technological
qualities of the cotton variety 1298, region-
alized in the Azerbaydzhan SSR, are given.
The author explains it by the circumstance that
self pollination is the prevailing biological
particularity of the variety 1298. It is
recommended, when introducing new cotton

Card 1/3

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6332

varieties, to take into account the degree of
cross pollination, which plays an important
role in the increase of productivity. The
study of new prospective for Azerbaydzhan
varieties (2421, 2018/2, C-1472, 2523) leads
to the conclusion that the majority of these,
along with self pollination for 2 - 3 hours
before the opening of flowers, are also cap-
able for cross pollination for 10 - 40%. It
is recommended for elite farms and seed culti-
vating kolkhozes, in order to obtain the most
viable plants, to utilize cotton in the middle
layers and the bolls of middle sympodia,
having superior qualities. It is necessary to
have one family of bees every 2 - 3 ha of

Title : The Determination of the Time for Irrigating
Cotton Growing with Narrow Spaces Between Rows

Orig Pub : Sots. s.-kh. Uzbekistana, 1957, No 7, 10-16

Abstract : A field experiment was carried out at the
Ak-Kavak Agrotechnical Station of the All-
Union Cotton Scientific Research Institute
in order to compare the effectiveness of
various methods of determination of the time
of cotton irrigating. The following methods
were tested: according to the soil moisture
70 - 70 - 60% and 65 - 70 - 60%, according to

Card 1/3

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6333

the exterior signs of the state of the plant and according to the sum of the medium daily temperatures during the period of blooming-fruit bearing. The spraying variant, according to the scheme 2-5-1, served as control. The experiment was carried out with cotton 108-f variety with the two following arrangements 60 x 50 x 3 (100,000 plants on 1 ha) and 50 x 50 x 3 (120,000 plants on 1 ha). It was established that the lowest average daily water rate and smaller irrigation norm were obtained with sprayings, according to the moisture of the soil and to the sum of the daily average temperatures. The number of sprayings was one less with these methods,

Card 2/3

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

khlopkovodstvu, 1957 g., Tashkent, AN Uzb SSR,
1957, 235-239

Abstract : Individual leaves were treated with chemical
preparations by immersion or vacuum-infiltra-
tion. The whole plant was also sprayed in
the case of the 108-f variety in the period
when 2 - 4 bolls open. Phenylthiourea and

Card 1/3

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6335

sodium diethyldithiocarbamate (0.5% solutions),
dicarboxylic acids and their derivatives-
fumaric and maleic acids, hydrazide of maleic
acid, diethyl ethers of fumaric and maleic
acids (0.02% solutions) did not display de-
foliation capacities. Calcium cyanamide
(2 and 5%) and sodium cyanamide (0.5 and 1.0%),
methylenedotal (0.2%) as well as thiourea
(0.5%) acted on direct contact, but endotal
(0.2%) had an over-all effect. It acted on
all leaves situated above the ones which
were treated directly. The defoliation agents
caused dehydration of cells. This process
grows with the increase in concentration. The
greatest dehydration was caused by cyanamide

Card 2/3

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6335

salts, magnesium chlorate and endotal. Methyl-
endotal stimulated absorption of CO₂ without
lowering the breathing intensity in view of
the activation of the oxydizing system; other
defoliation agents impede the photosynthesis
and breathing. An exception was found in
thiourea, which activated respiration through
the catalase system, after having inhibited
its first phase. -- B. E. Kravtsova

Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6336

of nitrification proceeded at a moderate rhythm and with increased intensity; the usual damping in certain vegetation periods of the cotton plant was avoided when 200 and 500 mg were introduced. However, the nitrification process was impeded when 1000 mg were introduced in a vessel. Uranium inhibits growth in the initial phase of development of the cotton plant, but it stimulates it during the fruit bearing and ripening phases, increasing the number of fruit buds by 14 - 17% in comparison with the control. It also increases the yield of cotton wool (in the field experiments) by 1.7 - 4.7 cwt/ha. Uranium prolongs the budding and blooming phases in the cotton

Title : Contribution to the Problem of the Study
of Wild Hemp in Order to Improve Cultivated
Hemp on a Selective Basis
Orig Pub : Tr. Bashkisk. s.-kh. in-ta, 1957, 8, No 2,
67-74

Abstract : A study of the biology of the wild hemp showed
that it is substantially different from the
cultivated variety. The seeds of cultivated
hemp lose all their germinating capacity,
when they remain in the soil at a depth of
over 15 cm for two years. In the case of wild

Card 1/3

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6339

hemp, this capacity is preserved by 26 - 48%
of the seeds. After harvesting, the
ripening period in the seeds of wild hemp is
much longer than in those of the cultivated
hemp. The germinating capacity of the seeds
of wild hemp continues to exist after 5 years
of storage. However, the seeds of cultivated
hemp lose this capacity after 3 years. The
stigma's period of receptivity to pollen
and the conservation of fecundity is almost
twice as long in the case of the wild hemp
as in the cultivated type. Wild hemp produces
10 - 20% more seeds and 10 - 13% more fiber
than the cultivated variety. It is more
resistant to hemp flea-beetles (Psylliodes

Orig Pub : Tr. Vses. n.-i. in-ta lub. kul'tur, 1957,
vyp 22, 179-205

Abstract : Cross breeding of forms of gambo hemp of varying origins and different biological and ecological features causes heterosis in the first and subsequent generations. The maximum manifestation of heterosis is observed in the cross breeding of very early ripening or early ripening forms with very late

Card 1/2

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6341

ripening ones. Late ripening is a dominant feature in F₁. Early ripening gambo hemp varieties, which were characterized by the rapid initial growth of their plants, were separated from the hybrid material. This feature appeared to be recessive. A gambo hemp variety, Kubanskiy 333, which is highly productive and has a good yield of fiber, was obtained as a result of selection from a combination exhibiting heterosis. To eliminate the prickliness of gambo hemp, which is its dominant feature, hybridization with related species of the genus Hibiscus (furcaria section), which has almost no prickles, was carried out. -- S. Ya. Krayevoy

(in Poland), Which Were Carried Out in 1950-1955

Orig Pub : Wydawn. wlasne. Inst. uprawy, nawozenia i
gleboznawstwa, 1957, No 61, 5-28

Abstract : Old and new oleaceous crops, cultivated in Poland were studied. It is best to sow winter rape during the period between August 15th and 25th. Nitrogen fertilizers used in the cultivation of winter rape should be introduced on two separate occasions: in the fall (the smaller dose) and in the spring

Card 1/2

POLAND / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6344

(the greatest portion of the required dose).
The yield of seeds increased with the increase
of the dose of N up to 175 kg/ha. Winter
gold-of-pleasure, which has a high winter
resistance, was selected for cultivation from
a number of weeds. The best yield and the
best quality of oil obtained from 16 summer
oleaceous plants came from sunflowers and
Ethiopian colewort (*Crambe abissinica*).
Perilla, rocketsalad and lallemantia were
found to be unfit for cultivation. Economical
methods of harvesting sunflower and castor
plants were developed. -- A. M. Smirnov

Abstract : The sunflower varieties number 15659, 15636
and others selected by the Institute took
first place in the competitive variety trial
in 1956 (city of Krasnodar). Oiliness had been
calculated in absolutely dry seeds. The variety

Card 1/2

USSR / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6346

number 16652 produced more oil than the best
competitive varieties during the preliminary
variety tests. Early ripening varieties with
a high degree of oiliness were sorted out in
the first year nursery. The oiliness calculated
on absolutely dry seeds reached 52 - 53.6%
in some high yielding numbers. In 1956
certain numbers of intervariety hybrids proved
themselves to be resistant to rust in
addition to being highly productive. --

Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6348

the highest was 50% greater for all 3 elements.
The width of the spaces between rows was 60
and 50 cm and the distance in rows was 20, 30
and 40 cm. The increase in doses of fertilizer
in comparison with the lowest amount did not
increase the productivity and oiliness of the
plant. The highest yield of seeds was obtained
when the plants were disposed according to
the following diagram: 60 x 40 and 60 x 30.
The yield was higher when the distance between
rows was 60 cm, than 50 cm. The highest
degree of oiliness was obtained when the
plants were disposed as follows: 60 x 30 cm.

Title : Data on the Analysis of the Yield of Flax

Orig Pub : Magyar tud. akad. Agrartud. oszt. közl.,
1957, 13, No 1-2, 129-145

Abstract : Studies conducted over a period of 3 years on the analysis of the crop of many varieties and types show that the yield of flax seeds is the result of the following four main components: 1) the absolute weight of seeds, 2) the number of seeds in a boll, 3) the number of bolls on the plant, 4) the density of plants. A formula for the determination of the yield

Card 1/2

HUNGARY / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6354

in accordance with the above is given. As was shown by the studies, the first two components (1st and 2nd) are stable-hereditary, the last two (3rd and 4th) depend on external conditions. The number of bolls in a plant has the decisive influence on the yield of seeds. The yield of fiber can be calculated by using the method of microscopical study of anatomic structure of the plant or by dissection of the fibers on an individual stem. Formulas for determining the yield of fiber are also given. -- F. Yu. Grabar'

Title : Top Dressing Summer Rape with Nitrogen

Orig Pub : Wydawn. własne, Inst. uprawy, nawożenia i
gleboznawstwa, 1957, No 61, 127-133

Abstract : Following variants of introduction of N were
applied in field experiments (1953-1955):
1) 20 before sowing, 2) 40 before sowing,
3) 60 before sowing, 4) 20 before sowing + 40
before formation of buds, 5) 40 before sowing
+ 20 before formation of buds, 6) 20 before
sowing + 40 before blooming, 7) 40 before
sowing + 20 before blooming, 8) 20 before sowing

Card 1/2

POLAND / Cultivated Plants. Commercial, Oleaceous,
Sugar Bearing.

M-4

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6359

+ 20 before formation of buds + 20 before
blooming. The introduction of N was always
effected with a background of P₃₀ and K₆₀.
The division of the application of N in two
doses (before sowing and in the budding period)
had no effect on the yield. The division of
the dose in three equal parts (before sowing,
before budding and before blooming) produced
the greatest increase of yield. The fat
content of seeds diminished with the increase
in the dose of N. The greatest decrease
took place, when N was introduced before the
period of formation of buds or before blooming.
The doses and the time of introduction of N had
little effect on the absolute weight of seeds.

Abstract : Higher productivity, early ripening and slow
opening of the bolls during ripening were
noticed in new sesame varieties numbers 412,
320 and 798 during the competitive variety
tests held in 1954-1956 (city of Krasnodar).
The yield of many new early ripening strains

Card 1/2

as recorded during the initial selection links
in 1956, was 8.2 - 9.5 cwt/ha as compared with
the yield of the control Kubanets variety
of 4.6 - 5.8 cwt/ha. The majority of inter-
specie hybrids had greater yields of seeds
than their parental species in 1956. --

1957, 64-69

Abstract : Experiments on the amelioration of VNIIMK-165
variety castor made it possible to achieve a
more harmonious ripening, taller plants and
a decrease in the number of lateral racemes.
Experimental harvesting with combines, which

Card 1/2

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6365

was carried out at the Kolkhoz "Kuban'".
Ust-Labinskiy Rayon, Krasnodar Kray in 1955,
showed that VNIIMK-165 variety, which took
the first place with regard to the yield of
seeds among the three varieties (VNIIMK-165,
Early Hybrid and Sangvineus 401) was charac-
terized by its tall stems and by the prevalence
of monoracemous plants. The damage to the
seeds inflicted during the harvesting was the
smallest. This variety was recognized as the
most suitable for harvesting with combines. --

Abstract : Field experiments, which took place at experimental stations of the higher agricultural school in Poznan during 1950-1954, as well as experiments in various soil-climatic zones of Poland showed that there was no substantial difference in yield and oiliness of seeds, when perilla was sowed during the period between

Card 1/2

POLAND / Cultivated Plants. Technical.

M-5

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6369

April 15th and May 15th in doses of 5 - 15 kg/ha (at intervals between rows of 33 cm). It is preferable to carry out the sowing earlier (not later than the end of summer grain crop sowings) due to the length of the vegetation period. Perilla requires more daylight and is therefore an unreliable crop for Poland. Relatively more favorable conditions for its cultivation exist in the southwestern part of the country. -- A. M. Smirnov

Title : The Increase of Sugar Beet Yields by Means
of Regulated Crop Rotations

Orig Pub : Mitschurinbewegung, 1958, 7, No 3, 101-107

Abstract : Bringing sugar beet sowing up to 240 t/ha
[sic!] and the productivity up to 320 cwt/ha
is one of the agricultural goals of the GDR.
Crop rotation is of particular importance to
the increase in productivity; it is of paramount
importance in resisting nematodes. The plants
which can attract nematodes must occupy a
minimum of area, no more than 20 - 25 of
the crop rotation area. At the same time, it

Card 1/2

GDR / Cultivated Plants. Technical.

M-5

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6379

is necessary to increase the area occupied by plants which are enemies of nematodes. The purity of fields from weeds also guarantees the success of the resistance to nematodes. Preceding crops are of great importance. Potatoes fertilized with manure represent the best preceding crop; winter rye with an introduction of manure directly under beets is the next best. Winter wheat is considered as the best preceding crop among the grain crops. An analysis of 3 examples of 10-field crop rotations with one or one and a half fields of beet is given. -- G. Yu. Dinesman

Title : Data on the Characteristics of the Sugar Beet Growth in Western Beet-Sowing Districts of the Bielorussian

Orig Pub : Tr. Grodnensk. s.-kh. in-ta, 1957, vyp 3, 49-55

Abstract : Experiments carried out by the Department of Plant Cultivation of the Grodno Agricultural Institute in 1953-1955 show that in the western districts of the Bielorussian, daily increments of sugar beet roots during the fall are greater than in the beet sowing districts of the Ukraine. Taking into account, the direct

Card 1/3

USSR / Cultivated Plants. Technical.

M-5

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6380

relation which exists between the development of the tops and the yield of roots, it is necessary to keep the maximum number of leaves on the plant before harvesting, in order to obtain a high yield of sugar beets in Bielorussia. In order to obtain this result, it is necessary to create an agrotechnical background, which will guarantee an increment in weight for well developed tops which will not be less than that of roots up to September 1st - 10th. After that date (up to the end of the harvest of the crop) there should be a rapid outflow of assimilation products from the leaves into the roots. In dry years it is very important to keep the assimilation activity of the sugar beet leaves at least until September 20 - 25th.

Title : Cultivation of One Seed Beets in the Altay
Forest-Steppe

Orig Pub : Sb. stud. nauchn.-rabot Altaysk. s.-kh. in-t,
1957, vyp 6, 9-16

Abstract : The effectiveness of growing one seed sugar beets (a mixture of seeds of Bielotserkovskiy and Yaltushkovskiy varieties) compared to the common multi-seed beet of the B541 variety was studied at the Kosikhin sugar beet sovkhos of Altay Kray in 1955. One-seed sugar beets were sown at the rate of 15 and 30 kg/ha and the usual norm is 30 kg/ha. The sowing took place

Card 1/2

USSR / Cultivated Plants. Technical.

M-5

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6381

on May 12th. One-seed sugar beet produced a yield of 300.3 cwt/ha with a sowing norm of 30 kg/ha. Common beets produced only 232 cwt/ha with identical saccharinity (14%). The amount of manual work involved in digging, testing and harvesting in one-seed sugar beets was 32% less than in the case of common sugar beets on the average. When one-seed sugar beets were sown in quantities of 15 kg/ha, the yield was 231 cwt/ha and the saccharinity was 14.05. The amount of work necessary to grow this variant is not indicated. --

Title : Changes in Yield and in Quality of Parental Sugar Beets According to the Disposition of Plants and the Fertilizer Bases in the Mikhaylovskiy Sovkhoz

Orig Pub : Zap. Voronezhsk. s.-kh. in-ta, 1957, 27, No 2, 269-272

Abstract : The combination of humus (before cultivation) and mineral fertilizer used in rows and of top dressing produced the heaviest roots (350 g) and the greatest planting density (100.8 thousand/ha), but the smallest saccharinity (18.8%). The introduction of phosphorous

Card 1/3

USSR / Cultivated Plants. Technical.

M-5

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6382

fertilizers alone in rows and in the top dressing sharply diminished the weight of the roots (down to 210 g) but increased the saccharinity (up to 19.4%) when the density of plants was 97.9 thous/ha. Large doses of Naa are harmful in the fertilization of rows. They have an adverse effect on germination and decrease the density of plants (down to 90.5 thous/ha). The greatest density of plants (89.6 thous/ha, sic!) was obtained in beds which had a surface of 44.5 x 18 cm. The weight of the roots was 238 g and the saccharinity was 15.5%. The least density of plants (42.8 thous/ha) was observed when the plants were disposed in squares of 44.5 x 44.5 cm. The heaviest roots (350 g) and the

Card 2/3

USSR / Cultivated Plants. Technical.

M-5

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6382

smallest saccharinity (15%) were observed in this case. With the variant of 44.5 x 44.5 cm, intermediate values were obtained in the case of two plants. The increase in saccharinity of 0.4% obtained by introducing PK as additional top dressing, when the plants are disposed in a square, is worth consideration. The experimental was carried out at the Voronezh Agricultural Institute. -- N. I. Orlovskiy

varietal breeding. Seeds from the roots of the B632 variety alone, grown at the Uladovo-Lyulinets Station were used as control. The cross breeding was carried out when plants left to run to seed were grown in laboratories in winter with additional electric light and then under natural field conditions. The testing of seeds grown in this manner was carried out during the usual spring sowing period with winter plants left to seed. The trials were made at the time of summer sowing (July 20th) with spring plants under field conditions. The increase in yield and the amelioration of quality of seeds was highest in the case of intervarietal cross breeding and somewhat lower for intravarietal cross breeding. An increase in the yield of

Orig Pub : S.-kh. Sibiri, 1958, No 2, 68-70
Abstract : Stem grafted rennet-apple orchards perish during their 14th - 15th year in Siberia. However, seedlings and rooted trees produced with cuttings or root scions (from rooted plants), live up to 60 years and are highly productive. This method of propagation, verified at the Omsk Agricultural Institute, is recommended.

Title : The Formation of Accessory Buds on the Roots
of an Apple Tree

Orig Pub : Vestn. Mosk. un-ta, Ser. Biol., pochvoved.,
geol., geogr. 1957, No 1, 53-62

Abstract : The anatomical picture of the setting, formation and development of buds of wild apple trees from Kamyshin and of wild apples from the Moscow suburbs on the roots of Dwarf apple, Paradiska 9 and Kitayka in the city of Michurinsk was studied. Many sprouts were formed when horizontal roots were damaged on

Teas.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6414

the examined apple tree species. The picture of setting, formation and development of accessory root buds in various apple tree species is identical. The embryos of buds are formed in the parenchymal tissue, which can be bast and radial parenchyma or parenchyma of the secondary bark, situated under the cork. Meristematic embryos develop in buds and grow in sprouts most intensively on roots which are 4 - 10 mm thick. When the root is thicker or thinner, they constitute a store of "dormant buds". Mass bud setting on damaged or cut roots can be utilized for apple tree propagation by means of root scions. -- I. K. Fortunatov

anise apple variety were grafted on them, and scions of cultivated pear trees were grafted on the wild pear trees in the spring of 1953. The extension of the bud scales and the opening of buds started earlier on the lower stages of the top and on the grafting made on them. The increment of annual sprouts, water supply of sprouts and leaves, and transpiration intensity were greater in the lower stages of the top. The leaves of the upper stages of the mentor and of the grafts made on them were more xeromorphic. They were characterized by a greater suctorial power, greater osmotic pressure, drought resistance and suffered less from water scarcity. -- I. K. Fortunatov

Soil on the Rootstocks of the Mazzard
Cherry Tree

Orig Pub : Byul. nauchno-tekhn. inform. Dagestansk.
n.-i. in-ta s.-kh., 1957, No 1, 5-8

Abstract : Observations on Mazzard cherry tree (*Prunus avium*) plantings, conducted in southern Dagestan, showed that the cultivated cherry tree, grafted on the wild one, produces tall and long lasting trees. They produce high yields,

Card 1/2

USSR / Cultivated Plants. Fruits, Berries, Nutbearing, M-6
Teas.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6427

but consume a great deal of water. When the Mazzard cherry is grafted on the sour cherry (*Prunus cerasus*), it produces trees of medium height, which supports low salinity and is a good fruit bearer. When it is grafted on the Mahaleb cherry, it produces trees of medium height; they enter rapidly into the phase of commercial fruit bearing and are very productive. They are more drought resistant than those grafted on the first two root-stocks, but they are less salt-resistant.

Title : Growth and Development of the Root Systems
of Various Peach Tree Stocks in the Crimean
Steppe

Orig Pub : Byul. nauchn. inform. Gos. Nikitsk. sad,
1957, No 5-6, 53-57

Abstract : The strength and character of the structure
of root systems and the dynamics of the growth
of active roots in their yearly growth cycle
in peach, apricot, almond and myrobalan plum
trees, on which Alberta and Ak-Sheftalyu No
3 peaches were grafted, were studied during

Card 1/4

USSR / Cultivated Plants. Fruits, Berries, Nutbearing, M-6
Teas.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6431

1952-1955. Excavations were carried out according to the "monolith" method and the active roots were studied according to the "arbitrary monolith" method. Plants grafted on peach and apricot trees produced a stronger root system starting in their first years of growth on non-irrigated, dark chestnut, weakly saliferous soil. The main mass of the root system on all studied stocks was disposed in layers A and B. The degree of development of the root system is closely connected with the growth norm of the surface organs. 4 subsequent periods in the annual growth cycle of the root system of the stocks were established. The spring-summer maximum of growth of roots

Card 2/4

USSR / Cultivated Plants. Fruits, Berries, Nutbearing, M-6
Teas.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6431

takes place over a period of $2\frac{1}{2}$ months for peach trees, $2\frac{1}{2}$ - 3 months for almond and apricot trees, and $3\frac{1}{2}$ - 4 months for the plum trees. The summer slow-down of the growth of the root system is explained by the increase in the temperature (over 21°) and by the lowering of the moisture of the soil. The length of this period is 2 months for apricot and peach trees, $1\frac{1}{2}$ - 2 months in the case of almond trees, and $2\frac{1}{2}$ months for plum trees. The fall maximum in root growth takes place over a period of $2\frac{1}{2}$ months for the almond and plum trees and 3 months for peach and apricot trees. The growth of the root system slows down in the winter because of the lowering of

Card 3/4

USSR / Cultivated Plants. Fruits, Berries, Nutbearing, M-6
Teas.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6431

the soil temperature down to $+5^{\circ}$. The growth of the root system stops in the winter when the soil temperature descends down to $+2^{\circ}$. Soil watering and the introduction of fertilizers should be coordinated with the beginning of the accelerated period of growth of the root system of every stock species. It is necessary to carry out the fall plowing in the peach orchard before the beginning of the period of growth of active roots in the fall, but not later than 1 - $1\frac{1}{2}$ months before the end of this period. -- I. Title : The Fertilization of Grapes

Orig Pub : Agrartudomány, 1956, 8, No 7, 299-302

Abstract : The possibility of replacing manure by other organic fertilizers was studied. Rubbish, straw, crushed vine, turf, lignite, reed combined with mineral fertilizers were used. Experiments took place in Kecskemet on sandy soil, in Tokaihegyalja - on argillaceous soil, in Eger on neutral soils and in Badacson - on sierozem soils. Whenever manure was not applied at least once every 3 - 4 years, any

Card 1/3

HUNGARY / Cultivated Plants. Fruits, Berries,
Nutbearing, Teas.

M-6

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6452

combinations with other fertilizers remained ineffective. Artificial organic fertilizers were placed in the fall into the soil at a depth of 25 - 30 cm and were covered with a layer of mineral fertilizers. In most variants, the humification of organic substances had started already during the first year and finished during the third year. The increment in yield on loess-like soils of Tokaihegyalja, on plots which had received 15 t/ha of lignite dust mixed with NPK (N_c 0.4 t/ha, P_c 0.6 t/ha, K_c 0.2 t/ha), was 27% in comparison with plots which had received only mineral fertilizers. In the variant involving crushed vine (15 t/ha)

Card 2/3

Moldavii, 1957, No 4, 38-39

Abstract : Several authors (P. K. Soldatov, O. I. Matvereva and others) indicated that the high productivity of shrubs does not hold in their posterity, if the mother shrubs did not have different morphological features than poorly productive shrubs. This would negate the possibility of clonal selection by productivity features. However, experiments

Title : Local Black Fetyaska Variety

Orig Pub : Sadovodstvo, vinogradarstvo i vinodeliye
Moldavii, 1958, No 2, 37-38

Abstract : The Black Fetyaska variety is widespread near Kishenev (Moldavian SSR) and in Rumania. The growth potential and productivity are high. The mildew resistance is the same as in the white Fetyaska variety. The root system is powerful. The shrubs with their own roots are capable of regeneration. The variety has good potential for wine production.

Title : Study of Dry Pruning of Rootstocks of Grapevines

Orig Pub : Comun. Acad. RRP, 1957, 7, No 8, 727-732

Abstract : It was established at the experimental stations of viniculture of Dragashan and Krachunel (Rumania) in 1951-1954 that the dry pruning of grapevine stocks (Berlandieri x Riparia Teleki 8B and Berlandieri x Riparia Cober 5BB, Riparia Gloar), when small branches of 2 cm with two and 4 buds are left, causes the vegetation of shrubs to

Card 1/3

RUMANIA / Cultivated Plants. Fruits, Berries,
Nutbearing, Teas.

M-6

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6461

begin 8 - 10 days earlier in comparison with the control (pruning without branches left). The more branches were left, the greater the average increment of sprouts was, up to the moment of the first cultivation. The growth and the size of sprouts in prunings where small branches were kept, especially if they were 2 cm long, were more uniform, than in variants where the branches were removed. The greatest yield of stock scions (with hilling of shrubs) was obtained by pruning and by keeping branches of 2 cm long (178.000), the smallest yield resulted from short pruning (without branches) - 171.500 scions from 1 ha. It is recommended to hill the shrubs for the winter

Orig Pub : Tr. Sukhumsk. zonal'n. opytn. st. efiro-maslichn. kul'tur, 1957, vyp 2, 145-149

Abstract : The results of experiments on the cultivation of pink geranium (*Pelargonium roseum* Willd.) in Armenia at the Oktemberyanskiy base of ZOS are given in this paper. The effect of the period and number of cuttings (mowings) on the yield of geranium was studied. The effect of the period of fall cuttings on

Card 1/2

USSR / Cultivated Plants. Medicinal. Essential Oil-
Bearing. Toxins.

M-7

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6488

hibernation, the development of the maximum sowing density, the effect of mineral fertilizers and the influence of preceding crops were also studied. It was established that by utilizing necessary cultivation practices, it is possible to obtain 25 - 30 tons of green mass and 26 - 32 kg of essential oil per ha. Growing of geranium styles by sowing plants in areas of 90 x 90 cm guarantees a yield of standard scions of up to 150 thousand per ha. This data as well as the data on geranium yields from model plots in some kolkhozes permits one to conclude that the cultivation and production of high yields of geranium is quite possible in the Ararat Valley. -- A. G. Vyatkina

Title : Contribution to the Problem of Geranium Selection

Orig Pub : Tr. Sukhumsk. zonal'n. opytn. st. efiro-
maslichn. kul'tur, 1957, vyp 2, 19-34

Abstract : Pink geranium (*Pelargonium roseum* Willd.) is characterized by a low yield of essential oil (0.11 - 0.12% of green mass), poor implanting capacity and the spread form of its shrubs, which makes mechanized soil cultivation difficult in the period of vegetation. New hybrid geranium forms with high oil

Card 1/3

USSR / Cultivated Plants. Medicinal. Essential Oil- M-7
Bearing. Toxins.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6489

contents which have $2\frac{1}{2}$ - 4 times more oil than pink geranium, and have a higher content of citronellol and geraniol, were developed at the Sukhumi Station of Essential Oil Crops, starting in 1937. The hybrids have good implanting properties (10% higher than pink geranium), high yields of green mass (25 t/ha), and the shrubs have a compact straight shape. This permits one to mechanize the cultivation of the plants and the harvestings of the crop. Part of the hybrids are being tested at the station at the present time; hybrids 220 k-15 and 229 k-40 are bred for subsequent delivery to industry; hybrid No 5 is being tried in the sovkhoses

Title : Methods of Growing Patchouli Seedlings

Orig Pub : Tr. Sukhumsk. zonal'n. opytn. st. efiro-
maslichn. kul'tur, 1957, vyp 2, 45-65

Abstract : The essential oil, which is contained in
leaves of patchouli (Pogostemon patchouli
Pell Saut) - a tropical perennial plant of
the mint family, is utilized by the perfume
industry as a stable fixer. Long stemmed
patchouli sets were received by the Sukhumi
Zonal Experimental Station from the island of
Java in 1932 and from that time on, the

Card 1/2

USSR / Cultivated Plants. Medicinal. Essential Oil- M-7
Bearing. Toxins.

Abs Jour : Ref Zhur - Biologiya, No 2, 1959, No. 6490

station has carried out experiments on the
study of its agrotechnical engineering and
methods of propagation. It was established
that in the Soviet subtropics, patchouli
must be cultivated as an annual crop. The
problems of temperature conditions during the
growth of the seedlings, the time for style
cutting, the technique of planting scions,
their fertilization, hardening, pinching
and other data are discussed in detail. On
the basis of data collected over a period
of many years, it is recommended to cultivate
patchouli seedlings in hothouses and in
ground greenhouses with heating during the
critical periods. -- A. G. Vyatkina

parations of DDT, benzene hexachloride and
many other highly effective synthetic in-
secticides the production of pyrethrum in
Kenya was sharply curtailed and only at
present it started to grow anew attaining
3400 t in 1955. Alletrine, a product of
syntheses of an allyl homolog of cinerine I,
which enters into composition of acting sub-
stances of pyrethrum, became for a large
part a rival of pyrethrum. Beside Kenya,
India also cultivates pyrethrum. Its need
in dry racemes is calculated at 4 - 6 thousand
tons. England is also a producer of pyrethrum.
The Rothamsted Agricultural Experimental

ch. 1, 3-10

Abstract : The problem of natural intergrowth of trees
(self grafting) and the expediency of its
utilization in ornamental ground construction
is discussed. In the distant past special
compact (dense) tree plantings were effected
in order to obtain intergrowths. The method
was used to improve the quality of fruits,
to increase the size of flowers and so on.

Examples of utilization of the method of intergrowth in garden-park construction in Germany are given. A description and characteristics of particulars of the growth and conditions of natural intergrowth of trees (Siberian firs, lindens, pines, white poplars, Himalayan cedars and others) in Leningrad and in other localities, according to the observations of the author in the course of 6 - 8 years are given. It was established by studies of the collective of the department that the trees of the first and second magnitude intergrown by their roots attain greater vigor, have an ampler fruit bearing capacity, produce better seeds, are more resistant to unfavorable conditions and
